Anatomy and Physiology Study Guide: Key Review Questions and Answers with Explanations – Volume 2 (Bone Tissue, Skeletal System, Muscle Tissue, Muscular System)

Welcome to the definitive study companion for students of anatomy and physiology. This guide is designed to deepen your understanding of the bone tissue and skeletal system, as well as the muscle tissue and muscular system. By blending clear explanations, concise summaries, and targeted review questions, you'll be equipped to master the material and excel on exams. Whether you're a first year biology major or a seasoned professional seeking a refresher, the structured layout and thoughtful practice questions will help you internalize complex concepts and apply them confidently.

Overview of Volume 2

Volume 2 of the Anatomy and Physiology study guide focuses on the structural and functional aspects of the musculoskeletal system. It is organized into four core sections:

- Bone Tissue – the cellular and molecular makeup of bone.
- Skeletal System – the arrangement and roles of bones in the body.
- Muscle Tissue – the types, structure, and innervation of muscle fibers.
- Muscular System – the mechanisms of contraction, energy supply, and adaptation.

Each section includes detailed descriptions, illustrative diagrams (described in text), and key review questions with thorough answers. By following this guide, you'll develop a holistic view of how the musculoskeletal system supports movement, protects organs, and maintains homeostasis.

Anatomy of Bone Tissue

Composition of Bone

Bone is a dynamic composite material composed of an organic matrix, primarily collagen type I, and an inorganic mineral phase, mainly hydroxyapatite crystals. The organic component provides tensile strength, while the mineral phase confers compressive resistance. This unique combination allows bone to withstand the mechanical forces of daily activity while remaining lightweight.

Cell Types in Bone

- Osteoblasts – bone forming cells that secrete collagen and mineralize the matrix.
- Osteoclasts – large multinucleated cells that resorb bone during remodeling.
- Osteocytes – mature bone cells embedded in lacunae that maintain bone tissue and sense mechanical strain.
- Bone marrow stromal cells – precursors to osteoblasts and adipocytes.

Bone Matrix and Mineralization

The bone matrix is a collagenous scaffold that undergoes mineralization through the deposition of hydroxyapatite crystals. The process is tightly regulated by signaling molecules such as osteocalcin, bone sialoprotein, and matrix Gla protein. Proper mineralization ensures optimal bone hardness and resistance to fractures.

Bone Growth and Remodeling

Bone growth occurs through two distinct processes:

1. Intramembranous ossification – direct differentiation of mesenchymal cells into osteoblasts, forming flat bones such as the skull.
2. Endochondral ossification – cartilage templates replaced by bone, responsible for long bone formation.

Remodeling is a continuous cycle of bone resorption by osteoclasts and formation by osteoblasts. This cycle is essential for repairing microdamage, adapting to mechanical loads, and regulating calcium homeostasis.

Physiology of the Skeletal System

Primary Functions

The skeletal system serves four fundamental functions:

1. Support – provides a framework for body shape and structure.
2. Protection – shields vital organs such as the brain, heart, and lungs.
3. Movement – acts as levers for muscle contraction, facilitating locomotion.
4. Mineral Storage – stores calcium and phosphorus for metabolic needs.

Bone Homeostasis and Calcium Regulation

Bone acts as a dynamic reservoir for calcium. When serum calcium levels drop, parathyroid hormone (PTH) stimulates osteoclast activity to release calcium into the bloodstream. Conversely, high calcium levels trigger calcitonin secretion from the thyroid gland, inhibiting osteoclasts and promoting bone formation. Vitamin D enhances intestinal calcium absorption, further influencing bone health.

Common Skeletal Disorders

- Osteoporosis – age related loss of bone density leading to fragility fractures.
- Osteoarthritis – degenerative joint disease characterized by cartilage breakdown.
- Paget’s disease – abnormal remodeling causing bone pain and deformities.
- Rickets/osteomalacia – defective mineralization due to vitamin D deficiency.

Anatomy of Muscle Tissue

Types of Muscle

Muscle tissue is categorized into three distinct types:

1. Skeletal muscle – voluntary, striated fibers attached to bones, enabling locomotion.
2. Cardiac muscle – involuntary, striated fibers of the heart, responsible for pumping blood.
3. Smooth muscle – involuntary, non striated fibers found in walls of hollow organs.

Structure of Skeletal Muscle Fibers

Skeletal muscle fibers are multinucleated, cylindrical cells composed of myofibrils. Each myofibril contains repeating units called sarcomeres, the fundamental contractile units. Sarcomeres are organized by Z lines, A bands, I bands, and the M line, giving skeletal muscle its characteristic striated appearance.

Neuromuscular Junction

The neuromuscular junction (NMJ) is the synapse between a motor neuron and a muscle fiber. Acetylcholine released from the neuron binds to receptors on the sarcolemma, initiating an action potential that propagates along the fiber, ultimately triggering muscle contraction.

Physiology of the Muscular System

Mechanism of Muscle Contraction

Muscle contraction follows the sliding filament theory:

1. Action potential reaches the NMJ.
2. Acetylcholine release depolarizes the sarcolemma.
3. Calcium ions are released from the sarcoplasmic reticulum.
4. Calcium binds troponin, shifting tropomyosin and exposing myosin binding sites.
5. Cross bridge cycling between actin and myosin generates tension.
6. ATP hydrolysis provides energy for the power stroke.

Energy Systems Supporting Contraction

Muscle contraction relies on three primary energy pathways:

- Phosphagen system – uses phosphocreatine for rapid ATP regeneration.
- Glycolytic system – anaerobic breakdown of glucose, producing lactate.
- Oxidative phosphorylation – aerobic metabolism of carbohydrates, fats, and proteins.

Muscle Adaptation and Training

Muscle fibers adapt to training stimuli:

1. Hypertrophy – increase in fiber size due to protein synthesis.
2. Hyperplasia – increase in fiber number, more common in certain species.
3. Neural adaptations – improved motor unit recruitment and firing rates.

Resistance training favors type II fibers, whereas endurance training enhances type I fiber oxidative capacity.

Key Review Questions & Answers

Below are twenty essential review questions covering bone tissue, the skeletal system, muscle tissue, and the muscular system. Each question is followed by a concise answer and an explanation to reinforce learning.

Answer: Support, protection, movement, and mineral storage.

Explanation: The skeleton provides the structural framework for the body, protects organs, serves as levers for muscle action, and stores calcium and phosphorus.

Which cells are responsible for bone formation?

Answer: Osteoblasts.

Explanation: Osteoblasts synthesize collagen and secrete the organic matrix, which is later mineralized to form new bone tissue.

Describe the difference between intramembranous and endochondral ossification.

Answer: Intramembranous ossification involves direct bone formation from mesenchymal tissue, whereas endochondral ossification replaces a cartilage template with bone.
