Introduction

Artificial Neural Network–Fuzzy Inference System (ANFIS) is a powerful hybrid modeling technique that blends the learning ability of neural networks with the interpretability of fuzzy logic. Over the past decade, ANFIS has become a go-to method for engineers and data scientists tackling nonlinear system identification, time series forecasting, control, and pattern recognition tasks. MATLAB, with its robust Fuzzy Logic Toolbox and Neural Network Toolbox, provides a user friendly environment for implementing ANFIS models. In this tutorial, we'll walk through everything you need to know to build, train, and deploy an ANFIS model in MATLAB, from setting up your workspace to fine tuning the system for optimal performance.

What Is ANFIS?

ANFIS is a type of adaptive network that uses a Takagi–Sugeno fuzzy inference system (FIS) as its core. The network structure consists of five layers: input, fuzzification, rule, normalization, and output. During training, the network adjusts the parameters of the membership functions (MFs) and the consequent linear functions using a hybrid learning algorithm that combines back propagation and least squares estimation. The result is a model that can capture complex nonlinear relationships while retaining a fuzzy rule base that can be inspected and interpreted.

Why Use ANFIS in MATLAB?

MATLAB offers several advantages for ANFIS development:

- Integrated Toolboxes – The Fuzzy Logic Toolbox provides ready made functions for creating and visualizing fuzzy systems, while the Neural Network Toolbox offers the anfis function for training.
- Graphical User Interface (GUI) – The Fuzzy Logic Designer GUI allows you to construct a FIS visually, then export it to an ANFIS model.
- Extensive Documentation – MATLAB's help system and example notebooks cover a wide range of use cases.
- Performance – MATLAB's optimized matrix operations ensure fast training even for large datasets.

Prerequisites for ANFIS in MATLAB

Before diving into the tutorial, make sure you have:

- MATLAB R2015b or newer (older versions may lack certain functions).
- The Fuzzy Logic Toolbox installed.
- Basic knowledge of MATLAB syntax and plotting.
- An understanding of fuzzy set theory and neural network basics.

Setting Up MATLAB for ANFIS

Open MATLAB and add the Fuzzy Logic Toolbox to the path if it isn't already included:

1. Go to Home > Set Path.
2. Click Add Folder and navigate to the folder containing the toolbox.
3. Press Save and Close.

Verify the installation by running:

ver\\n\\nYou should see **Fuzzy Logic Toolbox** listed among the installed products.

Building an ANFIS Model: Step by Step Tutorial

We'll use a classic example: predicting a system output based on two inputs. The process is modular and can be adapted to any problem.

1. Define the Problem and Collect Data

Choose a dataset that exhibits nonlinear behavior. For demonstration, we'll generate a synthetic dataset:

%% Generate synthetic data\\nx1 = linspace(0, 10, 200)';\\nx2 = linspace(0, 5, 200)';\\nX = [x1, x2];\\ny = sin(x1) + log(x2 + 1) + randn(200,1)*0.1; % Add noise\\n\\nIn practice, replace this with your real measurements.

2. Create the Fuzzy Inference System (FIS)

Use the newfis function to create a Mamdani or Takagi–Sugeno FIS. For ANFIS, we'll use Takagi–Sugeno.

% Create a Takagi–Sugeno FIS\\nfis = newfis('anfis_example', 't-s');\\nfis = addvar(fis, 'input', 'x1', [0 10]);\\nfis = addvar(fis, 'input', 'x2', [0 5]);\\nfis = addvar(fis, 'output', 'y', [-2 2]);\\n\\n% Add membership functions (Gaussian)\\nfis = addmf(fis, 'input', 1, 'Low', 'gaussmf', [1 2]);\\nfis = addmf(fis, 'input', 1, 'High', 'gaussmf', [1 8]);\\nfis = addmf(fis, 'input', 2, 'Low', 'gaussmf', [0.5 1]);\\nfis = addmf(fis, 'input', 2, 'High', 'gaussmf', [0.5 4]);\\n\\n% Add rules\\nruleList = [1 1 1 1 1; 1 2 2 1 1; 2 1 3 1 1; 2 2 4 1 1];\\nfis = addrule(fis, ruleList);\\n\\nThe rule base can be expanded or refined based on domain knowledge.

3. Convert to ANFIS

Once the FIS is defined, convert it to an ANFIS structure that can be trained:

anfisModel = anfis([X y], fis, [200 0.01 0.01 0.01 0.01 0.01], 0);\\n\\nThe second argument is the training data. The third argument specifies training parameters: **epochs**, **stepSize**, **errorGoal**, **minStep**, **displayInfo**, **displayError**. Adjust these values to control training speed and convergence.

4. Train the ANFIS

The anfis function handles training internally. However, you can also call train on an existing ANFIS object for more control:

% Create training and validation sets\\n[trainInd, valInd] = dividerand(length(y), 0.7, 0.3, 0);\\ntrainData = [X(trainInd, :), y(trainInd)];\\nvalData = [X(valInd, :), y(valInd)];\\n\\n% Train\\n[trainedAnfis, trainError, stepSize, chkError] = train(anfisModel, trainData, valData, ...\\n 200, 0.01, 0.01, 0.01, 0.01, 0, 0);\\n\\nMonitor the error curves to ensure the model is learning properly.

5. Validate and Test

After training, evaluate the model on unseen data:

% Predict on validation set\\npredicted = evalfis(trainedAnfis, X(valInd, :));\\n\\n% Compute performance metrics\\nmse = mean((y(valInd) - predicted).^2);\\nrmse = sqrt(mse);\\nfprintf('Validation RMSE: %.4f\\\\n', rmse);\\n\\nPlot actual vs. predicted values to visually inspect the fit.

6. Fine Tune and Optimize

Common strategies for improving ANFIS performance include:

- Adjusting Membership Functions – Replace Gaussian MFs with triangular or trapezoidal if they better capture data distribution.
- Increasing Rule Base – Add more rules to capture subtle interactions.
- Using Different Learning Rates – Experiment with step sizes in the hybrid learning algorithm.
- Regularization – Apply a penalty term to prevent overfitting.
- Cross Validation – Use k fold cross validation to estimate generalization error.

Example: Predicting Temperature Using ANFIS

Let's apply ANFIS to a real world problem: forecasting indoor temperature based on outside temperature and humidity. Assume you have a CSV file weather.csv with columns OutsideTemp, Humidity, and IndoorTemp.
