asme p numbers for base metals in welding iiw india

Published: September 19, 2026 | Index ID: #-

Introduction

Welding is a critical process that joins metal components to form complex structures in industries ranging from oil and gas to aerospace and power generation. In the United States, the American Society of Mechanical Engineers (ASME) has established comprehensive codes and standards that govern the design, fabrication, inspection, and testing of welded structures. One of the key elements of the ASME Boiler and Pressure Vessel Code (BPVC) is the use of **P numbers**, which classify base metals and define the required welding procedures for each material.

In India, the Institute of Welding (IIW) plays a pivotal role in setting national standards for welding practice. When Indian projects require compliance with ASME regulations—especially for international clients or for structures that must meet global safety benchmarks—engineers must understand how to apply ASME P numbers correctly within the IIW India framework.

This article delves deep into **asme p numbers for base metals in welding iiw india**, offering a comprehensive guide that covers the fundamentals of ASME P numbers, their application to various base metals, and how they integrate with IIW India standards. Whether you are a welding engineer, a quality assurance professional, or a project manager, this resource will equip you with the knowledge to ensure code compliance, optimize welding procedures, and maintain the highest safety and quality standards.

Understanding ASME Welding Codes

The ASME BPVC is a codified set of rules that covers the entire lifecycle of pressure vessels, boilers, and piping systems. Within this code, **Section IX** focuses specifically on welding qualifications, while **Section XI**deals with inspection and testing of welded components. Together, these sections establish the foundation for welding procedure specifications (WPS), welder qualifications, and material specifications.

One of the unique features of the ASME BPVC is the systematic classification of base metals using **P numbers**. These alphanumeric codes provide a quick reference to the required welding procedure, the permissible welding process, and the necessary qualifications for each metal type. By referencing the correct P number, engineers can avoid costly rework, ensure regulatory compliance, and uphold the structural integrity of the final product.

What Are ASME P Numbers?

ASME P numbers are a series of codes that identify **base metal types and their corresponding welding requirements**. Each P number is structured as a letter followed by a two-digit number (e.g., P01, P22, P44). The letter typically indicates the general category of the metal (e.g., steel, stainless steel, nickel alloy), while the two digits provide a more specific classification.

These codes are defined in ASME BPVC Section XI, Table 2, and they serve several purposes:

- Standardization – Ensures that all welders, inspectors, and fabricators refer to the same material classification.
- Procedure Specification – Determines which welding processes (e.g., SMAW, GMAW, GTAW) are acceptable for a given base metal.
- Qualification Requirements – Identifies the necessary welder qualifications, test methods, and acceptance

criteria.

- Documentation – Facilitates traceability and auditability in the quality management system.

Classification of Base Metals in ASME Welding

ASME P numbers cover a wide range of base metals used in pressure vessels, piping, and structural components. The classification is grouped into several categories, each with its own set of welding guidelines.

- Carbon Steel (P01–P09) – Includes low alloy and high alloy steels used in boiler and pressure vessel construction.
- Low Alloy Steel (P10–P19) – Covers steels with controlled alloy additions for improved strength and corrosion resistance.
- Stainless Steel (P20–P29) – Encompasses a broad spectrum of austenitic, ferritic, and martensitic stainless steels.
- Nickel Alloys (P30–P39) – Includes alloys such as Inconel, Hastelloy, and Monel, which offer high-temperature and corrosion resistance.
- Titanium and Alloys (P40–P49) – Covers titanium and its alloys used in aerospace and chemical processing.
- Aluminum (P50–P59) – Includes various aluminum alloys used in structural and heat exchanger applications.
- Copper Alloys (P60–P69) – Covers brass, bronze, and other copper-based alloys.
- Specialty Alloys (P70–P79) – Includes alloys such as Incoloy, Monel, and other high-performance materials.

ASME P Numbers for Common Base Metals

Carbon Steel

Carbon steels are the workhorse of the welding industry, especially in power plants and refineries. The most frequently used P numbers for carbon steel are **P01** (A516 Grade 70) and **P02**(A516 Grade 80). These designations correspond to the following:

- P01 – A516 Grade 70 – Used for pressure vessels up to 3000 psi.
- P02 – A516 Grade 80 – Used for vessels up to 6000 psi.

Both P01 and P02 allow welding processes such as Shielded Metal Arc Welding (SMAW), Gas Tungsten Arc Welding (GTAW), and Gas Metal Arc Welding (GMAW), provided the welder has the appropriate qualification.

Low Alloy Steel

Low alloy steels are engineered for improved strength and corrosion resistance. Key P numbers include **P10** (A572 Grade 50) and **P12**(A572 Grade 55). These are typically used in structural applications where higher loads are expected.

- P10 – A572 Grade 50 – Common in structural steelwork.
- P12 – A572 Grade 55 – Provides higher yield strength.

Stainless Steel

Stainless steels are essential for environments where corrosion resistance is paramount. The most common P numbers for stainless steel are **P20** (Type 304) and **P22**(Type 316). These codes dictate the welding process and filler material requirements.

- P20 – Type 304 – Austenitic stainless steel used in general-purpose applications.
- P22 – Type 316 – Contains molybdenum for enhanced corrosion resistance in chloride-rich environments.

Nickel Alloys

Nickel alloys are prized for their high-temperature performance and corrosion resistance. The key P numbers in this category are **P30** (Inconel 718) and **P32** (Hastelloy C-276).

- P30 – Inconel 718 – Used in high-temperature gas turbines.
- P32 – Hastelloy C-276 – Offers excellent resistance to aggressive media.

Titanium and Its Alloys

Titanium is lightweight and has exceptional strength-to-weight ratio. The primary P number for titanium is **P40** (Grade 2). This code covers all welding processes that can be used with titanium, emphasizing the importance of clean work environments.

Non-Ferrous Metals (Aluminum, Copper, etc.)

Aluminum and copper alloys have unique welding challenges due to their high thermal conductivity. Key P numbers include **P50** (Aluminum 6061) and **P60** (Copper 1100).

- P50 – Aluminum 6061 – Widely used in aerospace and structural components.
- P60 – Copper 1100 – Common in electrical and heat exchanger applications.

Specialty Alloys (Inconel, Hastelloy, etc.)

Specialty alloys often require advanced welding techniques. The P numbers for these materials include **P70** (Inconel 625) and **P72** (Monel 400).

- P70 – Inconel 625 – Offers excellent corrosion resistance in seawater.
- P72 – Monel 400 – Known for high strength and corrosion resistance.

Determining the Correct P Number for Your Project
